The training-recipe study behind the released recipe, on the test windows (read before: a description, not a confirmation). All three recipes start from the same checkpoints (three seeds) trained from scratch with early stopping on the 93-day validation set. F and R then train exactly 8 more epochs: F on the unchanged training set (control); R, the released recipe, with the validation span returned to the training set. V instead re-splits with a proportional validation set (10% of the population's own record, 38–93 days) and stops early on it (5 to 30 epochs; the start weights count as epoch 0). Improvement of the first recipe over the second (unit-equal RMS ratio of the three-seed ensembles; positive = the first is better); 95% intervals combine the unit-and-month bootstrap with the spread over seeds (Welch); filled = interval excludes zero. Switch layer: short-record test windows whose season had no same-season month in the training set before the return and has one after it. On the four long-record populations V's validation set is the same 93 days.

Resolved against R: Six development populations, days 2–7, R vs F -1.35%. Lowest population estimate of R vs F (hourly): Drammen -2.9%.
