Each baseline's loss relative to ankyra-lite's on the same day, 100 (CV_model / CV_ankyra-lite − 1), from the curves of figure 9. ankyra-lite is the zero line by definition; its own loss, rising with the forecast day, is in figure 9. Above zero the baseline has the larger loss. Each panel has its own vertical scale. Over the whole month the comparison differs, because the monthly RMS weights days with large errors more. ankyra-lite 0.2.0: carrier recipe Rw (trained from scratch with early stopping on the 93-day validation set, then 8 more epochs with the validation span returned and each training window's loss weighted by the inverse-noise rule; six seeds averaged; figure 1b), the anchoring layer, the state rule and the origin-continuity layer; hourly errors score the delivered trajectory after that layer, energy, level and peak are read before it (readout rule A). Linear-context: the TiDE implementation of the release, whose forecast is a linear map of the load context.
