External tests of ankyra-lite 0.2.0: the 0.2.0 configuration re-run on the test sets of the frozen external test of 19 October 2026 (the same windows, comparators and estimators, read there once with the frozen candidate, recipe R with six seeds) and scored once on 20 October 2026. The carrier was trained anew for each test set with recipe Rw from the same stage-1 runs (six seeds averaged), under the unchanged anchoring layer, the seasonal-naive state rule and the origin-continuity layer (energy and peak read before the layer). LCL, UNICON and HKUST: previously read populations; GoiEner households out of time: a same-source out-of-time supplementary check (new households and a later period of study population 6), not a new population; Helsinki: trained, anchored and sealed, not scored. Improvement of the first forecaster's hourly error over the second (unit-equal RMS ratio; positive = the first lower); 95% intervals combine the unit-and-month bootstrap with the spread over seeds (Welch) where the record has a seed layer, else unit-and-month only; filled = the interval excludes zero (resolved), hollow = not resolved, which is not a finding of no difference; an interval end beyond the axis is drawn as an arrow. a–c: the three pre-specified primary readouts of each test set (12 nominal intervals over the four test sets, no multiplicity correction: with no true difference about 0.6 of them would be resolved by chance). d–f: the same contrasts by lead time, forecast hours 0–2 included. g–i: descriptive contrasts between ankyra-lite's own configurations by lead time (g: 0.2.0 against the 0.1.0 configuration; h: the continuation layer on against off; i: the loss weighting of recipe Rw against recipe R, without the layer). LCL is in the pretraining data of TimesFM 2.5, Chronos and Chronos-2, which favours TimesFM in a and d; whether GoiEner is in it is not verified; UNICON and HKUST are not on the published lists, which does not establish absence.

Windows / units / months of the primary readouts: LCL 710 / 710 / 5; UNICON 450 / 59 / 23; HKUST 89 / 29 / 8; GoiEner HH 1,417 / 282 / 6. Day-1 rule of the 0.2.0 design, written before the read (does the mean log gap to TimesFM 2.5 on forecast day 1 narrow, from the 0.1.0 configuration to 0.2.0, by at least a third of the development-set narrowing?): claim allowed (mean external shrink (log) 0.0848; line (1/3 of the development shrink) 0.0358). It allows only the statement that the day-1 gap narrowed, not a lead: on forecast day 1 ankyra-lite 0.2.0 against TimesFM 2.5 is LCL -10.4% (resolved worse); UNICON -13.3% (not resolved); HKUST -1.4% (not resolved); GoiEner HH -2.0% (not resolved).
