Peak readout $U = \max_d (\hat{L}_d + A_{\tau_d})$: ankyra-lite's daily means plus the largest recent excursion of the same day type (the anchoring layer's readout). Unit-equal improvement in absolute peak error with 95% unit-and-month intervals. a, b: blue better, red worse, open or grey not resolved. a: against the maximum of ankyra-lite's own delivered trajectory (after the continuation layer); the readout U is read before the layer (readout rule A). b: against the previous month's observed peak. c: against the same readout applied to each baseline's trajectory (the release rule), all 20 baselines (21 forecasters). Bold: the six release test populations (shaded). ankyra-lite 0.2.0: carrier recipe Rw (trained from scratch with early stopping on the 93-day validation set, then 8 more epochs with the validation span returned and each training window's loss weighted by the inverse-noise rule; six seeds averaged; figure 1b), the anchoring layer, the state rule and the origin-continuity layer; hourly errors score the delivered trajectory after that layer, energy, level and peak are read before it (readout rule A).
